1. Introduction

Typst [1] is “a new markup-based typesetting system that is powerful and easy to learn.” While Typst provides a built-in `table()` function, it does not currently support more advanced features such as row spans and column spans, fine-grain control of borders, or complex cell alignments. Pg Biel’s `tablex` project [2] provides many of these features. However, it remains the case that writing a table using either `table()` or `tablex()` can require rather verbose syntax.

The `tbl.typ` project is an effort to allow the expression of rich tables in Typst using a more terse syntax. This syntax comes from a UNIX heritage: the `tbl` preprocessor which designed for use with the traditional TROFF typesetting system [3] [4] [5]. Important differences between the syntax of traditional `tbl` and `tbl.typ` are noted [later in this document](#).

After importing the library using `#import "tbl.typ"`, the basic format of a table when using `tbl.typ` is the following:

```
```tbl
Format specifications .
Data
```
```

The two main components of this syntax are:

- *Format specifications*. This describes the layout of the table in terms of the number and style of columns for each row.

The last line of the format specifications must end in a period (`.`). This is the separator between the two sections.

- *Data*. This is the content that will fill each cell of the table. Generally every input line in this section corresponds to a row in the table, though there are exceptions noted later. Cells are separated by the `tab` option which defaults to a TAB character.

2. Region options

In addition to the overall [table syntax](#) itself, you may specify *region options* that control the parsing and styling of the table as a whole using a “show-everything” rule prior to the tables you would like to control. For example:

```
#show: tbl.template.with(
  allbox: true,
  tab: "|",
)
```

The following options are recognized:

auto-lines,
allbox Like [box](#), but also draw a line between every cell if **true**. This is the same option from [tablex](#).

Default: **false**
cf. Example 10, 11, 12, 13.

box,
frame If **true**, draw a line around the entire table.

Default: **false**
cf. Example 1, 2, 3, 4, 5.

breakable,
nokeep If **true**, the table can span multiple pages if necessary.

Default: **false**

center,
centre Aliases for a [tbl-align](#) value of **center**.

decimalpoint The string used to separate the integral part of a number from the fractional part. Used in [N](#)-classified columns.

Default: **"."**

doublebox,
doubleframe Like [box](#), but also draw a second line around the entire table if **true**.

Default: **false**
cf. Example 14.

font The font for the table. Can be overridden later by the [f\(...\)](#) column modifier.

Default: **"Times"**
n.b. all tables in this document are formatted with the New Computer Modern font.

| | |
|-----------------------------------|---|
| header-rows | The number of rows at the beginning of the table to consider part of the “header” for the purposes of <code>repeat-header</code> . This option is also controlled by <code>.TH</code> rows in the table data.

<i>Default:</i> <code>1</code> |
| leading | The vertical spacing / leading to apply to table cells. Can be overridden later by the <code>v(...)</code> column modifier. |
| macros | A dictionary of (name, function) pairs that can be used with column modifier <code>m(...)</code> .

<i>Default:</i> <code>(:)</code> |
| pad | This is the padding used for each cell, for use with the Typst <code>pad</code> element function. The <code>left</code> and <code>right</code> keys can be overridden using a numeric column modifier .

<i>Default:</i> <code>(left: 0.75em, right: 0.75em, top: 3pt, bottom: 3pt)</code> |
| repeat-header | If <code>breakable</code> is <code>true</code> and this option is <code>true</code> , then the table header controlled by <code>header-rows</code> will be re-displayed on each subsequent page. This option is also controlled by <code>.TH</code> rows in the table data.

<i>Default:</i> <code>false</code> |
| stroke,
linesize | How to draw all lines in the table.

<i>Default:</i> <code>1pt</code> |
| tab | The string delimiter that separates different cells within a given row of the table data.

<i>Default:</i> <code>"\t"</code> (a TAB character)
<i>cf. Example 14. Most tables in this document use <code>" "</code> (a vertical bar) for readability purposes, though this should not be confused with the column classifier of the same name.</i> |
| tbl-align | How to align the table as a whole.

<i>Default:</i> <code>left</code> |

3. Format specifications

The format specifications section controls the layout and style of cells within rows and columns of the table.

Each comma or new line of format specification begins a new *row definition*. Within each row definition, encountering a *column classifier character* denotes a new column in the table. The classifier may be followed by any number of *column modifiers*, some of which may have required arguments enclosed in parentheses.

3.1. Column classifiers

The following column classifiers are recognized. They may be given as either capital or lowercase.

| | |
|----------|--------------------|
| L | Left align. |
| R | Right align. |
| C | Center align. |
| N | Numerically align. |

All cells with this classifier in the current column are centered with respect to an *alignment point*, which is determined according to the following rules:

- One position after the leftmost occurrence of the *non-printing input token* `\&`, if any is present.
- Otherwise, the rightmost occurrence of the `decimalpoint` string that immediately precedes a digit.
- Otherwise, the rightmost digit.
- Otherwise, the content is instead centered with respect to the column as a whole.

The alignment point is centered horizontally with respect to the column as a whole.

cf. Example 3, 4, 8, 9, 10, 14.

| | |
|----------|--|
| S | This cell is column-spanned by the previous cell to the left in the current row. |
|----------|--|

*The corresponding table data entries should be empty.
cf. Example 4, 5, 10, 12, 14.*

| | |
|---|---|
| ^ (caret) | This cell is row-spanned by the corresponding cell in the previous row above.

<i>The corresponding table data entries should be empty.
cf. Example 1.</i> |
| _ (underscore),
- (hyphen) | This cell contains a vertically-centered horizontal rule.

<i>The corresponding table data entries should be empty.</i> |
| = (equals sign) | Same as _ , but draw a double horizontal rule instead.

<i>The corresponding table data entries should be empty.</i> |
| (vertical bar) | This classifier does not actually begin a new column, but rather indicates the location of a vertical line.

If placed at the beginning of a row definition, the line is drawn to the left of the first cell in that row. Otherwise, it is drawn to the right of the current cell in that row.

<i>cf. Example 1, 3, 4, 5, 8.</i> |

3.2. Column modifiers

The following column modifiers are recognized. They may be given as either capital or lowercase.

| | |
|---------------|--|
| b | Bold text using the Typst strong element function. |
| d | Down — set the vertical alignment to bottom . |
| e | Equalize the width of all columns with this modifier to the maximum width among those columns.

This overrides modifier x . |
| f(...) | Font name to use is given in parentheses.

f(B) is an alias for the b modifier.
f(I) is an alias for the i modifier.
f(BI) is an alias for providing both of the above modifiers.

<i>cf. Example 12.</i> |
| i | Italicize text using the Typst emph element function. |

m(...) Macro (function) to apply to each corresponding cell. The macros must be scoped using the `macros` region option.

The macro currently only receives a single argument: the content of the cell. A future version may also pass the position of the cell in terms of row number and column number.

o(...) Fill color for the cell is given in parentheses.

cf. Example 11.

p(...) Point size of the font is modified according to the argument in parentheses.

If the argument begins with a `+` or `-`, then the argument is added or subtracted respectively with respect to the current size.

The argument may be suffixed by a unit. If no unit is specified, `pt` is assumed. Valid units are:

- `pt`, `p`: points.
- `mm`: millimeters.
- `cm`, `c`: centimeters.
- `in`, `i`: inches.
- `em`, `m`: `1em` corresponds to the current font size.
- `en`, `n`: one *en* equals half of an em.
- `P`: six *picas* equals one inch.
- `M`: 100 of these equals one em.

cf. Example 8, 12, 14.

t Top — set the vertical alignment to `top`.

cf. Example 12.

u “Stagger” the affected cells so that they appear **between** the current row and the previous one above.

cf. Example 7.

v(...) Vertical spacing (leading) is modified according to the argument in parentheses.

The length argument provided is in the same format as `p(...)`, with a default unit of `pt` and `+` / `-` relative adjustments supported.

w(...) Width of the column is guaranteed to be at least as big as the argument in parentheses, which acts as a *minimum width*.

The length argument provided supports the same units as **p(...)**, with a default unit of **en**. However, relative adjustments are **not** supported.

This overrides modifier **x**.

cf. Example 12, 13.

x Expand the width of the column to **1fr**, which will consume all of the remaining horizontal space on the page or in the current container. Applying this modifier to multiple columns will divide that remaining space evenly between them.

This overrides modifiers **e** and **w(...)**.

z The corresponding cell is treated as if it has **zero** width for the purpose of determining the width of its column.

cf. Example 1.

Number A number given as a column modifier is interpreted as a **en length** which is used as a *column separation*. This is the distance that separates the end of the current cell's content from the beginning of the next cell's content. If there is a vertical line between the two cells, then it will appear centered on this separation distance.

The default column separation is controlled by the sum of the **left** and **right** keys of the **pad** option. When not specified, this defaults to **0.75em + 0.75em**, which traditional TROFF calls **3n**.

cf. Example 13, 14.

4. Data

Each input line following the terminating `.` of the `format specifications` creates a new row of data in the table, with each cell separated by the `tab` string.

4.1. Special input lines

Some input lines do not represent table rows at all:

- A line consisting of only `_` (underscore) draws a horizontal line at that position in the table. This is only useful if `auto-lines` is `false`.

cf. Example 3, 4, 5, 14.

Similarly, `=` (equals sign) in TROFF would draw a double horizontal line, but this is not currently supported.

- A line consisting of only `.TH` (period + capital T + capital H) is an *end-of-header* marker. All rows of data that precede it are considered part of the table's header for the purposes of the `header-rows` option. It also sets `repeat-header` to `true`. This is only useful if `breakable` is also `true` and the table spans multiple pages.
- A line consisting of only `.T&` (period + capital T + ampersand) in TROFF marks the beginning of a new set of format specifications to be terminated by `.` and more table data to follow, but this is not currently supported.
- Lines that begin with `.\"` (period + backslash + double quote) are treated as comments and completely ignored.
- Other lines that begin with `.` (period) in TROFF were used as *commands* (*requests* or *macro invocations*), but this cannot be supported for obvious reasons. Any such line is rejected. To have the first cell in a row begin with a period, use a Typst escape like `\.` or put a SPACE in front of it.

4.2. Table entries

The string representing the cell content is called the *table entry*. For the most part, this is simply passed to the Typst `eval` function, so you can use Typst markup within a table entry. There are a few important caveats:

- The `eval` function does not have access to anything other than the Typst standard library. This means it is not currently possible to reference variables or functions within a table entry.
- [Numerically-aligned cells](#) are split on the alignment point and then evaluated as two separate pieces of content. This may cause unexpected syntax errors if you have Typst markup that spans the alignment point.
- The `tab` string cannot be used **within** a table entry, except by using Typst hexadecimal escape sequences (provided that `tab` is not any of `\`, `u`, `{`, `}`, a letter, or a digit).
- Any occurrences of the string `\&` (backslash-ampersand; known as the *non-printing input token*) in the table entry are removed.

4.3. Special table entries

If certain characters are alone in a table entry, they gain a special meaning:

- `_` (a single underscore): Draw a horizontal line through the middle of this otherwise empty cell. The line touches any adjacent vertical lines that are present.

cf. Example 5, 8, 13.

- `_` (backslash + underscore): Like `_` above, but the line does **not** touch any adjacent vertical lines, subject to the current [column separation](#).

cf. Example 13.

- `=` (equals sign): Like `_` above, but draw a double horizontal line.

cf. Example 13.

- `\=` (backslash + equals sign): Like `=` above, but subject to column separation like `_` above.

- `\^` (backslash + caret): This cell is row-spanned by the corresponding cell in the previous row above. This is similar to the `\^` column classifier, but can be used at an arbitrary point in the table.

cf. Example 4.

4.4. Text blocks

A table entry can also span multiple input lines by writing it as a *text block*. This consists of beginning the entry with `T{` (capital T + open brace), followed immediately by the end of that input line. All following input lines are collected as part of the text block until a input line that begins with `T}` (capital T + close brace) is encountered. The rest of that input line can provide the remaining entries for that row of the table.

If the cell is subject to the `w(...)` column modifier, then the text block is constrained to the specified width.

Otherwise, a constraining width W is calculated according to the following formula:

$$W = L \times \frac{C}{N - 1}$$

where L is the maximum width of the table based on the container it is in, or the width of the page minus the margins if there is no container; C is the number of columns this text block spans horizontally; and N is the total number of columns in the table.

cf. Example 12, 13.

5. Differences from traditional `tbl`

- [Region options](#) must be specified using a “show-everything” rule; they cannot be provided within the `raw` block itself.
- The `tab` option may be a multi-character string.
- The `linesize` option is expected to be a Typst color, length, or stroke; a dimensionless number does not work.
- The alignment point of [numerically-centered cells](#) that are in the same column as [left-centered](#) or [right-centered](#) cells is always centered with respect to the column as a whole (as if the classifier was `C`), rather than with respect to the widest `L` or `R` entry.
- All [column modifiers](#) that expect an argument must provide that argument in parentheses.
- The `o(...)` column modifier is a `tbl.typ` extension.
- Nothing special needs to be done to use equations within table entries, though [numerically-aligned columns](#) may behave unexpectedly until the `delim` option is implemented.
- An empty entry in the table data must be given even if the cell is spanned or contains a horizontal line.
- `\Rx` table entries are not handled. Use the Typst `repeat` element function instead, though this does not work well at the moment without a fully-functioning `w(...)` column modifier (see [Known issues](#)).

6. Known issues

- The following [region options](#) are not currently supported:
 - `delim` ([GH#1](#))
 - `expand` ([GH#2](#))
 - `nospaces`
 - `nowarn`
- The `pad` region option currently requires the `left` and `right` keys to be explicitly provided. Unexpected behavior may occur if `x` is provided as a key. ([GH#3](#))
- The following [column classifiers](#) are not currently supported:
 - `A` (alphabetic)
 - `||` (double vertical line)
- You may need to apply the `e` column modifier to one or more of the rightmost columns in order to minimize their width. This appears to be a more fundamental issue with Typst or `tablex` at the moment.
- The `w(...)` (minimum width) column modifier currently only sets the width of text blocks; it does not yet affect other table cells. ([GH#5](#))
- The `x` (expand) column modifier does not currently constrain the width of text blocks like it should.
- `.T&` in the [table data](#) is not currently supported. ([GH#4](#))
- Within text blocks, `.\"` comments are not removed, and other TROFF commands are not rejected. ([GH#6](#))
- A table data row consisting of only `=` (double horizontal line) is not currently supported.

7. Examples

The following examples are formatted with these region options:

```
#show: tbl.template.with(box: true, tab: "|")
```

Example 1: adapted from [4]

```
```tbl

#show: tbl.template.with(doublebox: true, tab: " : ")
```

Example 14: adapted from [5, p. 45]

```
```tbl
cb s s s s
cp(-2) s s s s
c | c | c | c | c
c | c | c | c | c
r2 | n2 | n2 | n2e | nbe.
Readability of Text
Line Width and Leading for 10-Point Type
-
Line : Set : 1-Point : 2-Point : 4-Point
Width : Solid : Leading : Leading : Leading
-
9 Pica : 93 : --6.0 : --5.3 : --7.1
14 Pica : 450 : --0.6 : --0.3 : --1.7
19 Pica : 5 : --5.1 : 0.0 : --2.0
31 Pica : 3 : --3.8 : --2.4 : --3.6
43 Pica : 5.1 : --90000.000 : --5.9 : --8.8
```
```

| Readability of Text | | | | |
